

Hands-on Lab: Updating Linux

Estimated time needed: 20 minutes

Learning Objectives

After completing this lab, you will know how to:

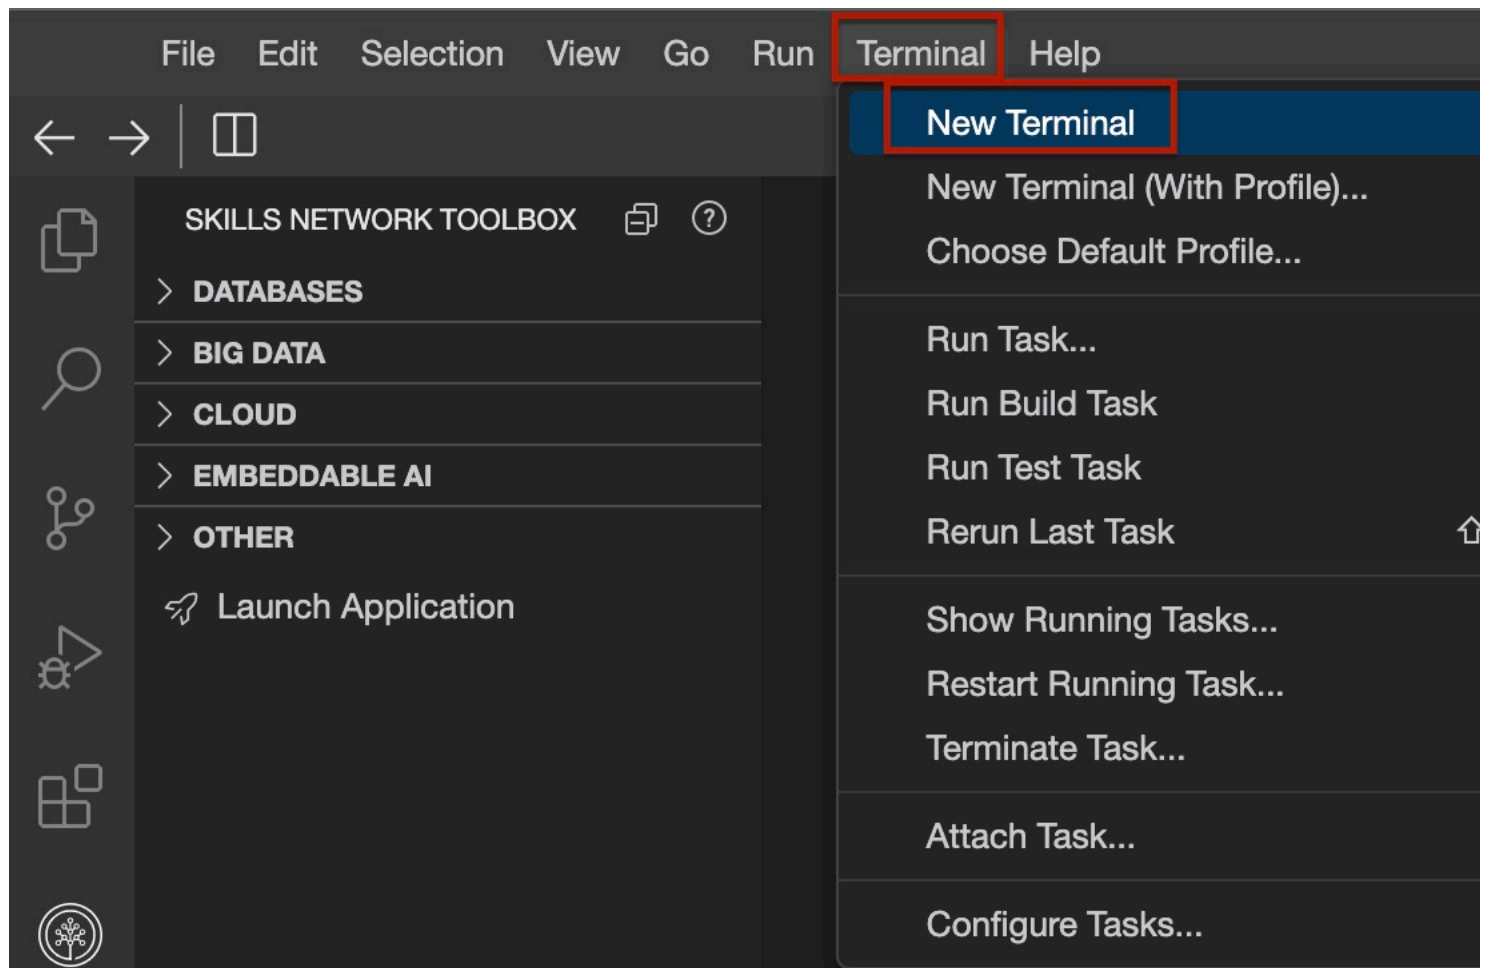

- Update package lists
- Perform Linux system upgrade

Prerequisites

This lab requires Docker, which is preinstalled in the Skills Network lab environment.

Update package lists

1. Open a new terminal.

2. The **apt update** command in Linux is used to update the local package index with the latest changes made in the repositories. This command retrieves information about available package versions from the system's configured repositories. If there is a new version, the system marks it for download and installation. The command does not upgrade or install any packages. In the new terminal that opens up, run the following command to update the package lists.

```
sudo apt update
```

This update will take a few seconds.

3. The `apt list --upgradable` will tell you which packages are available for upgrade. Run the following command to see a list of available updates and packages.

```
apt list --upgradable
```

Perform System Upgrade

1. The **apt upgrade** command in Linux is used to upgrade the installed packages and the Linux kernel to the latest versions. When you run this command, your system installs the updates for each outdated package and its dependencies. Run the following command to perform a system upgrade.

```
sudo apt upgrade
```

Note: Type 'Y' to continue with upgrading the installed packages.

*After completing upgrades, you would normally want to reboot your system. You could do so using the **sudo reboot** command (Note that this command will not work in the Cloud IDE environment.)*

Conclusion

Congratulations! In this lab, you have learned how to update Linux package lists and how to perform a Linux system upgrade.
