

# Cisco Cyber Threat Trends Report

**Estimated duration:** 5 minutes

## About the Cisco Cyber Threat Trends Report

The Cisco Cyber Threat Trends analysis is based on DNS activity observed by organizations using Cisco Umbrella. This report identifies top cybersecurity threats as information stealers, trojans, ransomware, remote access trojans (RATs), advanced persistent threats (APTs), botnets, and droppers. These threats use various methods, such as phishing, malicious links, and exploiting vulnerabilities to compromise systems.

The report states that information stealers secretly collect sensitive personal and financial data. Trojans and RATs provide backdoor access for attackers to install additional malware or spy on users. The report explains that ransomware encrypts files and demands payment, and APTs focus on long-term espionage and intellectual property theft. Botnets and droppers aid in large-scale attacks and malware distribution, respectively, demonstrating the evolving nature of these threats.

The report reveals that cybercriminals continually update and deploy security measures to evade detection, relying on techniques such as social engineering and advanced coding. Threat analysis shows changing activity patterns, often tied to cybercriminal strategies such as data analysis or campaign shifts. Despite efforts to combat these threats, their profitability, stealth, and adaptability ensure their ongoing prevalence in the cybersecurity landscape, posing significant challenges for organizations worldwide.

With a data-driven approach to these threats, the report outlines the average monthly blocks for each threat and provides insights into methods of breaching systems.

## Review the report

Open the following link to read the [Cisco Cyber Threat Trends Report](#) and learn more about top cybersecurity threats. Take some time to review this report, as it is invaluable for cybersecurity learners and professionals.
