

Glossary: Access Management and Endpoint Security

Estimated time needed: 5 minutes

Term	Definition
Access control	A mechanism that determines which operations the user can or cannot do by comparing the user's identity to an access control list (ACL). Access controls encompass file permissions, program permissions, and data permissions
audit	Involves using commands on your system and accessing log and journal information. You can create a special profile to be used by someone doing a security audit of your system.
authentication	Any process by which a system verifies the identity of a user who wishes to access the system.
authorization	Determines whether an authenticated user has the right to operate on a specific resource in a secure domain.
Customer identity and access management (CIAM)	Helps create better customer experiences and build trust with seamless identity management.
endpoint	A device that connects to a computer network (computers, laptops, smartphones, and so on). These devices can be a potential entry point for cyber threats or attacks. Infrastructure devices such as routers, switches, and firewalls are not endpoints because they are not the endpoint of a data exchange.
federation	A relationship where the participating entities agree to use the same technical standard, enabling access to data and resources of one another. It comprises one or more service providers (SP) and an identity provider (IdP). An IdP is a partner in a federation that can authenticate the identity of a user. A service provider is a company or program that provides a business function as a service.
Identity Access Management (IAM)	A cybersecurity discipline that manages user identities and access permissions on a computer network. While IAM policies, processes, and technologies can differ between companies, any IAM initiative aims to ensure that the right users and devices can access the right resources for the right reasons at the right time.
Privileged Access Management (PAM)	Keeps your business secure. Whether you oversee IT compliance, ensure that IT infrastructure is performing, or protect endpoints from malicious activity, PAM is a top-of-mind concern.
role-based access	A method for restricting system access to authorized users.
Single Sign-on (SSO)	An authentication scheme enables users to log in to a session once, using a single set of login credentials, and gain secure access to multiple related applications and services during that session without logging in again.
User and Entity Behavior Analytics (UEBA)	A type of security software that uses behavioral analytics, machine learning algorithms, and automation to identify abnormal and potentially dangerous user and device behavior. UEBA is particularly effective at identifying insider threats (malicious insiders or hackers using compromised insider credentials) that can elude other security tools because they mimic authorized network traffic.
User Behavior Analytics (UBA)	Monitors user activity, such as logins, file access, network activities, and other user actions. It then uses algorithms and statistical models to detect suspicious patterns in user behavior.
