

Glossary: Network, Application, and Data Security

Term	Definition
Application firewall	Helps protect web applications by filtering and monitoring HTTP traffic between a web application and the internet.
Cryptography	Converting between readable text, called plaintext, and an unreadable form, called ciphertext. This occurs as follows: The sender converts the plaintext message to ciphertext. This part of the process is called encryption (sometimes encipherment).
Demilitarized Zone (DMZ)	A configuration that includes multiple firewalls to add layers of protection between a corporate intranet and a public network, such as the Internet.
DevOps lifecycle	A series of iterative, automated development processes, or workflows, executed within a larger, automated, and iterative development lifecycle designed to optimize the rapid delivery of high-quality software.
DevSecOps	Short for development, security, and operations. It automates security integration at every phase of the software development lifecycle, from initial design through integration, testing, deployment, and software delivery. DevSecOps represents a natural and necessary evolution in how development organizations approach security. In the past, security was 'tacked on' to software at the end of the development cycle (almost as an afterthought) by a separate security team. It was tested by a separate quality assurance (QA) team.
Dynamic Application Security Testing (DAST)	It is a black-box security testing method that takes the approach of a real attacker from outside. Typically, you conduct DAST using automated (DAST scanners) on live web applications and web services, preferably running on test environments.
firewall	A blockade between a secure internal network and an untrusted network such as the Internet. Most companies use a firewall to connect an internal network safely to the Internet, although you can also use a firewall to secure one internal network from another.
Network Address Translation (NAT)	Changes internal or private addresses to public or globally routable Internet Protocol (IP) addresses. The Universal Connection traffic can flow through a NAT to IBM. This is enabled automatically. NAT also translates to ports.
Packet filter	Limits the services to individual users when they log on to a network. Packet filtering can permit or deny access based on destination IP addresses, ports, or both.
proxy	A proxy server lessens network traffic by rejecting unwanted requests, forwarding requests to balance and optimize server workload, and fulfilling requests by serving data from the cache rather than unnecessarily contacting the true destination server.
SASE	A framework that converges network services, such as software-defined wide area networking (SD-WAN), with cloud-delivered network security technologies, such as cloud access security broker (CASB), firewall as a service (FWaaS), and zero trust network access (ZTNA), into a single, cloud-delivered service model. This revolutionary framework has the potential to accelerate digital business, serve as a foundational element to zero trust security, and protect users and devices as they access resources anytime, anywhere.
Software Bill of Materials (SBOM)	It is a nested inventory, a list of ingredients that comprise software components.
Stateful packet inspection	Examines source and destination addresses, port numbers, and status information. Then, by applying IF, ELSE, or ENDIF filter rules to these header flags, stateful systems can make filtering decisions in the context of an entire session rather than that of an individual packet and its header information.
Static Application Security Testing (SAST)	Refers to security testing that is performed without actually executing the target application.
Virtual Private Network (VPN)	Allows your company to securely extend its private intranet over the existing framework of a public network, such as the Internet. With a VPN, your company can control network traffic while providing important security features such as authentication and data.
